

Stanford CS224W: Graph as Matrix: PageRank, Random Walks and Embeddings

CS224W: Machine Learning with Graphs
Jure Leskovec, Stanford University
<http://cs224w.stanford.edu>

ANNOUNCEMENTS

- **Homework 1** will be released after class
- **Next Thursday (10/07):** Colab 1 due, Colab 2 out
 - **Do Colab 0!** It has almost everything you need to complete Colab 1.
- **Office hours:** we've added Zoom links to our OH calendar.
 - See <http://web.stanford.edu/class/cs224w/oh.html> for OH calendar, Zoom links, and QueueStatus link.

CS224W: Machine Learning with Graphs
Jure Leskovec, Stanford University
<http://cs224w.stanford.edu>

Graph as Matrix

In this lecture, we investigate graph analysis and learning from a matrix perspective.

- Treating a graph as a matrix allows us to:
 - Determine node importance via **random walk** (PageRank)
 - Obtain node embeddings via **matrix factorization (MF)**
 - View other **node embeddings** (e.g. Node2Vec) as MF
- **Random walk, matrix factorization and node embeddings are closely related!**

Stanford CS224W: PageRank (aka the Google Algorithm)

CS224W: Machine Learning with Graphs
Jure Leskovec, Stanford University
<http://cs224w.stanford.edu>

Example: The Web as a Graph

Q: What does the Web “look like” at a global level?

- **Web as a graph:**

- Nodes = web pages
- Edges = hyperlinks
- **Side issue: What is a node?**
 - Dynamic pages created on the fly
 - “dark matter” – inaccessible database generated pages

The Web as a Graph

The Web as a Graph

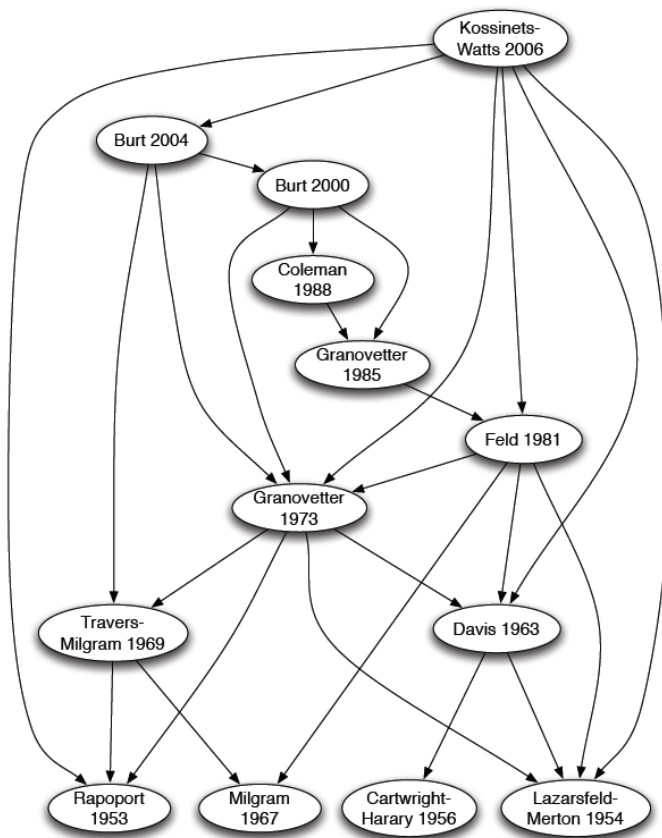

- In early days of the Web links were **navigational**
- Today many links are **transactional** (used not to navigate from page to page, but to post, comment, like, buy, ...)

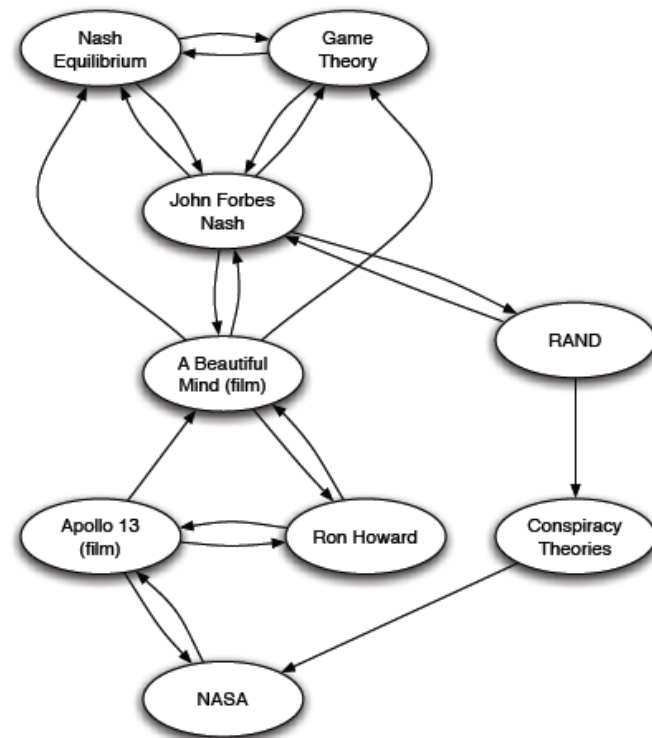

The Web as a Directed Graph

Other Information Networks

Citations

References in an Encyclopedia

What Does the Web Look Like?

- How is the Web linked?
- What is the “map” of the Web?

Web as a directed graph [Broder et al. 2000]:

- Given node v , what nodes can v reach?
- What other nodes can reach v ?

Ranking Nodes on the Graph

- All web pages are not equally “important”
thispersondoesnotexist.com vs. www.stanford.edu
- There is large diversity in the web-graph node connectivity.
- So, let's rank the pages using the web graph link structure!

Link Analysis Algorithms

- We will cover the following **Link Analysis approaches** to compute the **importance** of nodes in a graph:
 - PageRank
 - Personalized PageRank (PPR)
 - Random Walk with Restarts

Links as Votes

- **Idea: Links as votes**
 - Page is more important if it has more links
 - In-coming links? Out-going links?
- **Think of in-links as votes:**
 - www.stanford.edu has 23,400 in-links
 - thispersondoesnotexist.com has 1 in-link
- **Are all in-links equal?**
 - Links from important pages count more
 - Recursive question!

PageRank: The “Flow” Model

- A “vote” from an important page is worth more:
 - Each link’s vote is proportional to the **importance** of its source page
 - If page i with importance r_i has d_i out-links, each link gets r_i / d_i votes
 - Page j ’s own importance r_j is the sum of the votes on its in-links

PageRank: The “Flow” Model

- A page is important if it is pointed to by other important pages
- Define “rank” r_j for node j

$$r_j = \sum_{i \rightarrow j} \frac{r_i}{d_i}$$

d_i ... out-degree of node i

You might wonder: Let’s just use Gaussian elimination to solve this system of linear equations. Bad idea!

The web in 1839

“Flow” equations:

$$r_y = r_y/2 + r_a/2$$

$$r_a = r_y/2 + r_m$$

$$r_m = r_a/2$$

PageRank: Matrix Formulation

- **Stochastic adjacency matrix M**

- d_i is the outdegree of node i
- If $i \rightarrow j$, then $M_{ji} = \frac{1}{d_i}$
 - M is a **column stochastic matrix**
 - Columns sum to 1

- **Rank vector r :** An entry per page

- r_i is the importance score of page i
- $\sum_i r_i = 1$

- **The flow equations can be written**

$$r = M \cdot r$$

$$r_j = \sum_{i \rightarrow j} \frac{r_i}{d_i}$$

Example: Flow Equations & M

	r_y	r_a	r_m
r_y	$1/2$	$1/2$	0
r_a	$1/2$	0	1
r_m	0	$1/2$	0

$$r_y = r_y/2 + r_a/2$$

$$r_a = r_y/2 + r_m$$

$$r_m = r_a/2$$

$$\begin{matrix} r_y \\ r_a \\ r_m \end{matrix} = \begin{bmatrix} 1/2 & 1/2 & 0 \\ 1/2 & 0 & 1 \\ 0 & 1/2 & 0 \end{bmatrix} \begin{matrix} r_y \\ r_a \\ r_m \end{matrix}$$

$\mathbf{r} \qquad \qquad \mathbf{M} \qquad \qquad \mathbf{r}$

Connection to Random Walk

- **Imagine a random web surfer:**

- At any time t , surfer is on some page i
- At time $t + 1$, the surfer follows an out-link from i uniformly at random
- Ends up on some page j linked from i
- Process repeats indefinitely

$$r_j = \sum_{i \rightarrow j} \frac{r_i}{d_i}$$

- **Let:**

- $\mathbf{p}(t)$... vector whose i^{th} coordinate is the prob. that the surfer is at page i at time t
- So, $\mathbf{p}(t)$ is a probability distribution over pages

The Stationary Distribution

- Where is the surfer at time $t+1$?

- Follow a link uniformly at random

$$\mathbf{p}(t+1) = \mathbf{M} \cdot \mathbf{p}(t)$$

$$\mathbf{p}(t+1) = \mathbf{M} \cdot \mathbf{p}(t)$$

- Suppose the random walk reaches a state

$$\mathbf{p}(t+1) = \mathbf{M} \cdot \mathbf{p}(t) = \mathbf{p}(t)$$

then $\mathbf{p}(t)$ is **stationary distribution** of a random walk

- Our original rank vector \mathbf{r} satisfies $\mathbf{r} = \mathbf{M} \cdot \mathbf{r}$

- So, \mathbf{r} is a stationary distribution for the random walk

Recall Eigenvector of A Matrix

- Recall from lecture 2 (eigenvector centrality), let $A \in \{0, 1\}^{n \times n}$ be an adj. matrix of undir. graph:

$$A = \begin{pmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix}$$

- Eigenvector of adjacency matrix:
vectors satisfying $\lambda \mathbf{c} = A \mathbf{c}$
- \mathbf{c} : eigenvector; λ : eigenvalue
- Note:
 - This is the definition of eigenvector centrality (for undirected graphs).
 - PageRank is defined for directed graphs

Eigenvector Formulation

- The flow equation:

$$1 \cdot \mathbf{r} = \mathbf{M} \cdot \mathbf{r}$$

$$\begin{array}{|c|} \hline r_y \\ \hline r_a \\ \hline r_m \\ \hline \end{array} = \begin{array}{|ccc|} \hline 1/2 & 1/2 & 0 \\ \hline 1/2 & 0 & 1 \\ \hline 0 & 1/2 & 0 \\ \hline \end{array} \begin{array}{|c|} \hline r_y \\ \hline r_a \\ \hline r_m \\ \hline \end{array}$$

$\mathbf{r} \qquad \mathbf{M} \qquad \mathbf{r}$

- So the rank vector \mathbf{r} is an **eigenvector** of the stochastic adj. matrix \mathbf{M} (with eigenvalue 1)
 - Starting from any vector \mathbf{u} , the limit $\mathbf{M}(\mathbf{M}(\dots \mathbf{M}(\mathbf{M} \mathbf{u})))$ is the **long-term distribution** of the surfers.
 - **PageRank** = Limiting distribution = **principal eigenvector** of \mathbf{M}
 - **Note**: If \mathbf{r} is the limit of the product $\mathbf{M}\mathbf{M} \dots \mathbf{M}\mathbf{u}$, then \mathbf{r} satisfies the **flow equation** $1 \cdot \mathbf{r} = \mathbf{M}\mathbf{r}$
 - So \mathbf{r} is the **principal eigenvector** of \mathbf{M} with eigenvalue 1
- **We can now efficiently solve for \mathbf{r} !**
 - The method is called **Power iteration**

PageRank: Summary

- **PageRank:**
 - Measures importance of nodes in a graph using the link structure of the web
 - Models a random web surfer using the **stochastic adjacency matrix M**
 - PageRank solves $\mathbf{r} = M\mathbf{r}$ where \mathbf{r} can be viewed as both the **principle eigenvector of M** and as **the stationary distribution of a random walk** over the graph

Stanford CS224W: PageRank: How to solve?

CS224W: Machine Learning with Graphs
Jure Leskovec, Stanford University
<http://cs224w.stanford.edu>

PageRank: How to solve?

Given a graph with n nodes, we use an iterative procedure:

- Assign each node an initial page rank
- Repeat until convergence ($\sum_i |r_i^{t+1} - r_i^t| < \epsilon$)
 - Calculate the page rank of each node

$$r_j^{(t+1)} = \sum_{i \rightarrow j} \frac{r_i^{(t)}}{d_i}$$

d_i out-degree of node i

Power Iteration Method

- Given a web graph with N nodes, where the nodes are pages and edges are hyperlinks

- **Power iteration:** a simple iterative scheme

- Initialize: $\mathbf{r}^{(0)} = [1/N, \dots, 1/N]^T$

- Iterate: $\mathbf{r}^{(t+1)} = \mathbf{M} \cdot \mathbf{r}^{(t)}$

- Stop when $|\mathbf{r}^{(t+1)} - \mathbf{r}^{(t)}|_1 < \varepsilon$

$$r_j^{(t+1)} = \sum_{i \rightarrow j} \frac{r_i^{(t)}}{d_i}$$

d_i out-degree of node i

$|\mathbf{x}|_1 = \sum_1^N |x_i|$ is the **L1** norm

Can use any other vector norm, e.g., Euclidean

About 50 iterations is sufficient to estimate the limiting solution.

PageRank: How to solve?

■ Power Iteration:

- Set $r_j \leftarrow 1/N$
- 1: $r'_j \leftarrow \sum_{i \rightarrow j} \frac{r_i}{d_i}$
- 2: If $|r - r'| > \varepsilon$:
 - $r \leftarrow r'$
- 3: go to 1

■ Example:

$$\begin{bmatrix} r_y \\ r_a \\ r_m \end{bmatrix} = \begin{bmatrix} 1/3 \\ 1/3 \\ 1/3 \end{bmatrix}$$

Iteration 0, 1, 2, ...

	y	a	m
y	1/2	1/2	0
a	1/2	0	1
m	0	1/2	0

$$\begin{aligned} r_y &= r_y/2 + r_a/2 \\ r_a &= r_y/2 + r_m \\ r_m &= r_a/2 \end{aligned}$$

PageRank: How to solve?

■ Power Iteration:

- Set $r_j \leftarrow 1/N$
- 1: $r'_j \leftarrow \sum_{i \rightarrow j} \frac{r_i}{d_i}$
- 2: If $|r - r'| > \varepsilon$:
 - $r \leftarrow r'$
- 3: go to 1

	y	a	m
y	1/2	1/2	0
a	1/2	0	1
m	0	1/2	0

$$\begin{aligned}
 r_y &= r_y/2 + r_a/2 \\
 r_a &= r_y/2 + r_m \\
 r_m &= r_a/2
 \end{aligned}$$

■ Example:

$$\begin{bmatrix} r_y \\ r_a \\ r_m \end{bmatrix} = \begin{bmatrix} 1/3 \\ 1/3 \\ 1/3 \end{bmatrix} \quad \begin{bmatrix} 1/3 \\ 3/6 \\ 1/6 \end{bmatrix} \quad \begin{bmatrix} 5/12 \\ 1/3 \\ 3/12 \end{bmatrix} \quad \begin{bmatrix} 9/24 \\ 11/24 \\ 1/6 \end{bmatrix} \quad \dots \quad \begin{bmatrix} 6/15 \\ 6/15 \\ 3/15 \end{bmatrix}$$

Iteration 0, 1, 2, ...

PageRank: Three Questions

$$r_j^{(t+1)} = \sum_{i \rightarrow j} \frac{r_i^{(t)}}{d_i} \quad \text{or equivalently} \quad r = Mr$$

- Does this converge?
- Does it converge to what we want?
- Are results reasonable?

PageRank: Problems

Two problems:

- (1) Some pages are **dead ends** (have no out-links)
 - Such pages cause importance to “leak out”
- (2) **Spider traps** (all out-links are within the group)
 - Eventually spider traps absorb all importance

Does this converge?

- The “Spider trap” problem:

$$r_j^{(t+1)} = \sum_{i \rightarrow j} \frac{r_i^{(t)}}{d_i}$$

- Example:

Iteration:		0,	1,	2,	3...
r_a	=	1	0	0	0
r_b		0	1	1	1

Does it converge to what we want?

- The “Dead end” problem:

$$r_j^{(t+1)} = \sum_{i \rightarrow j} \frac{r_i^{(t)}}{d_i}$$

- Example:

Iteration:		0,	1,	2,	3...
r_a	=	1	0	0	0
r_b		0	1	0	0

Solution to Spider Traps

- **Solution for spider traps:** At each time step, the random surfer has two options
 - With prob. β , follow a link at random
 - With prob. $1-\beta$, jump to a random page
 - Common values for β are in the range 0.8 to 0.9
- **Surfer will teleport out of spider trap within a few time steps**

Solution to Dead Ends

- **Teleports:** Follow random teleport links with total probability **1.0** from dead-ends
 - Adjust matrix accordingly

	y	a	m
y	$\frac{1}{2}$	$\frac{1}{2}$	0
a	$\frac{1}{2}$	0	0
m	0	$\frac{1}{2}$	0

	y	a	m
y	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{3}$
a	$\frac{1}{2}$	0	$\frac{1}{3}$
m	0	$\frac{1}{2}$	$\frac{1}{3}$

Why Teleports Solve the Problem?

Why are dead-ends and spider traps a problem and **why do teleports solve the problem?**

- **Spider-traps** are not a problem, but with traps PageRank scores are **not** what we want
 - **Solution:** Never get stuck in a spider trap by teleporting out of it in a finite number of steps
- **Dead-ends** are a problem
 - The matrix is not column stochastic so our initial assumptions are not met
 - **Solution:** Make matrix column stochastic by always teleporting when there is nowhere else to go

Solution: Random Teleports

- Google's solution that does it all:

At each step, random surfer has two options:

- With probability β , follow a link at random
- With probability $1-\beta$, jump to some random page

- **PageRank equation** [Brin-Page, 98]

$$r_j = \sum_{i \rightarrow j} \beta \frac{r_i}{d_i} + (1 - \beta) \frac{1}{N}$$

d_i ... out-degree of node i

This formulation assumes that M has no dead ends. We can either preprocess matrix M to remove all dead ends or explicitly follow random teleport links with probability 1.0 from dead-ends.

The Google Matrix

- **PageRank equation** [Brin-Page, '98]

$$r_j = \sum_{i \rightarrow j} \beta \frac{r_i}{d_i} + (1 - \beta) \frac{1}{N}$$

- **The Google Matrix G :**

$[1/N]_{N \times N} \dots N$ by N matrix
where all entries are $1/N$

$$G = \beta M + (1 - \beta) \left[\frac{1}{N} \right]_{N \times N}$$

- **We have a recursive problem: $\mathbf{r} = G \cdot \mathbf{r}$**

And the Power method still works!

- **What is β ?**

- In practice $\beta = 0.8, 0.9$ (make 5 steps on avg., jump)

Random Teleports ($\beta = 0.8$)

$$0.8 \begin{bmatrix} 1/2 & 1/2 & 0 \\ 1/2 & 0 & 0 \\ 0 & 1/2 & 1 \end{bmatrix} + 0.2 \begin{bmatrix} 1/3 & 1/3 & 1/3 \\ 1/3 & 1/3 & 1/3 \\ 1/3 & 1/3 & 1/3 \end{bmatrix}$$

$$\mathbf{G} = \begin{matrix} & \begin{matrix} y & a & m \end{matrix} \\ \begin{matrix} y \\ a \\ m \end{matrix} & \begin{bmatrix} 7/15 & 7/15 & 1/15 \\ 7/15 & 1/15 & 1/15 \\ 1/15 & 7/15 & 13/15 \end{bmatrix} \end{matrix}$$

$$\begin{matrix} y \\ a \\ m \end{matrix} = \begin{matrix} 1/3 & 0.33 & 0.24 & 0.26 \\ 1/3 & 0.20 & 0.20 & 0.18 & \dots \\ 1/3 & 0.46 & 0.52 & 0.56 \end{matrix} \quad \begin{matrix} 7/33 \\ 5/33 \\ 21/33 \end{matrix}$$

PageRank Example

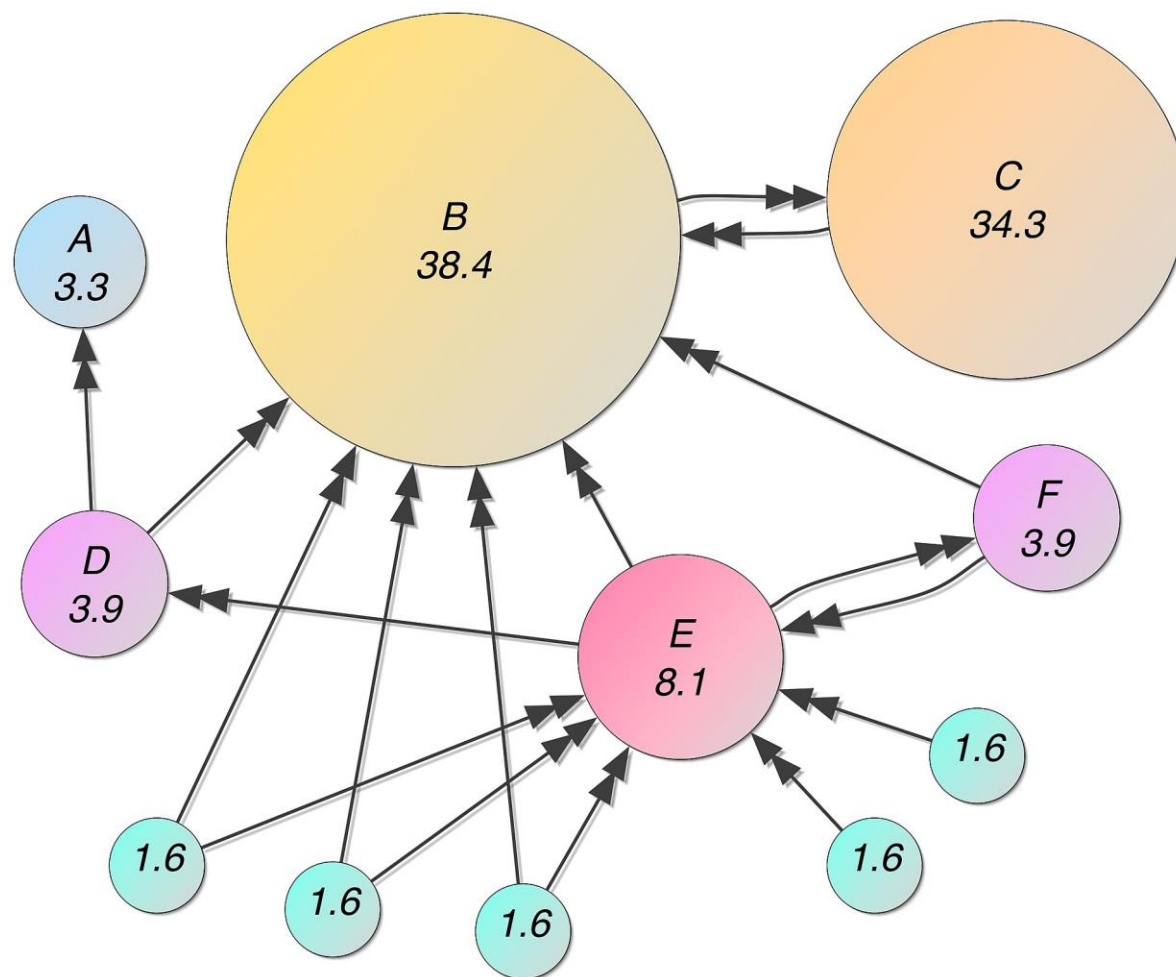

Image credit: [Wikipedia](#)

Solving PageRank: Summary

- PageRank solves for $\mathbf{r} = \mathbf{G}\mathbf{r}$ and can be efficiently computed by power iteration of the stochastic adjacency matrix (\mathbf{G})
- Adding random uniform teleportation solves issues of dead-ends and spider-traps

Stanford CS224W: Random Walk with Restarts and Personalized PageRank

CS224W: Machine Learning with Graphs
Jure Leskovec, Stanford University
<http://cs224w.stanford.edu>

Example: Recommendation

- **Given:**

A bipartite graph representing user and item interactions (e.g. purchase)

Bipartite User-Item Graph

- **Goal:** Proximity on graphs
 - What items should we recommend to a user who interacts with item Q?
 - **Intuition:** if items Q and P are interacted by similar users, recommend P when user interacts with Q

Bipartite User-to-Item Graph

- Which is more related A,A' or B,B'?

Node proximity Measurements

- Which is more related A,A', B,B' or C,C'?

Node proximity Measurements

- Which is more related A,A', B,B' or C,C'?

Node proximity Measurements

- Which is more related A,A', B,B' or C,C'?

Personalized Page Rank/Random Walk with Restarts

Proximity on Graphs

- **PageRank:**
 - Ranks nodes by “importance”
 - Teleports with uniform probability to any node in the network
- **Personalized PageRank:**
 - Ranks proximity of nodes to the teleport nodes S
- **Proximity on graphs:**
 - **Q:** What is most related item to **Item Q**?
 - **Random Walks with Restarts**
 - Teleport back to the starting node: $S = \{Q\}$

Idea: Random Walks

■ Idea

- Every node has some importance
- Importance gets evenly split among all edges and pushed to the neighbors:

■ Given a set of QUERY_NODES, we simulate a random walk:

- Make a step to a random neighbor and record the visit (visit count)
- With probability ALPHA, restart the walk at one of the QUERY_NODES
- The nodes with the highest visit count have highest proximity to the QUERY_NODES

Random Walks

- **Idea:**
 - Every node has some importance
 - Importance gets evenly split among all edges and pushed to the neighbors
- Given a set of **QUERY NODES Q**, simulate a random walk:

Random Walk Algorithm

■ Proximity to query node(s) Q :

$\text{ALPHA} = 0.5$

$\text{QUERY_NODES} = \{ \text{Q} \}$

```
item = QUERY_NODES.sample_by_weight()
```

```
for i in range( N_STEPS ):
```

```
    user = item.get_random_neighbor()
```

```
    item = user.get_random_neighbor()
```

```
    item.visit_count += 1
```

```
    if random( ) < ALPHA:
```

```
        item = QUERY_NODES.sample.by_weight( )
```

Random Walk Algorithm

■ Proximity to query node(s) Q :

ALPHA = 0.5

QUERY_NODES = { Q }

```
item = QUERY_NODES.sample_by_weight()
```

```
for i in range( N_STEPS ):
```

```
    user = item.get_random_neighbor()
```

```
    item = user.get_random_neighbor()
```

```
    item.visit_count += 1
```

```
    if random( ) < ALPHA:
```

```
        item = QUERY_NODES.sample.by_weight( )
```

Number of visits by
random walks starting at Q

Benefits

- Why is this a good solution?
- Because the “similarity” considers:
 - Multiple connections
 - Multiple paths
 - Direct and indirect connections
 - Degree of the node

Summary: Page Rank Variants

■ PageRank:

- Teleports to any node
- Nodes can have the same probability of the surfer landing:
 $S = [0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1]$

■ Topic-Specific PageRank aka Personalized PageRank:

- Teleports to a specific set of nodes
- Nodes can have different probabilities of the surfer landing there:

$$S = [0.1, 0, 0, 0.2, 0, 0, 0.5, 0, 0, 0.2]$$

■ Random Walk with Restarts:

- Topic-Specific PageRank where teleport is always to the same node:

$$S = [0, 0, 0, 0, 1, 0, 0, 0, 0, 0]$$

Summary

- A graph is naturally represented as a matrix
- We defined a random walk process over the graph
 - Random surfer moving across the links and with random teleportation
 - Stochastic adjacency matrix M
- PageRank = Limiting distribution of the surfer location represented node importance
 - Corresponds to the leading eigenvector of transformed adjacency matrix M .

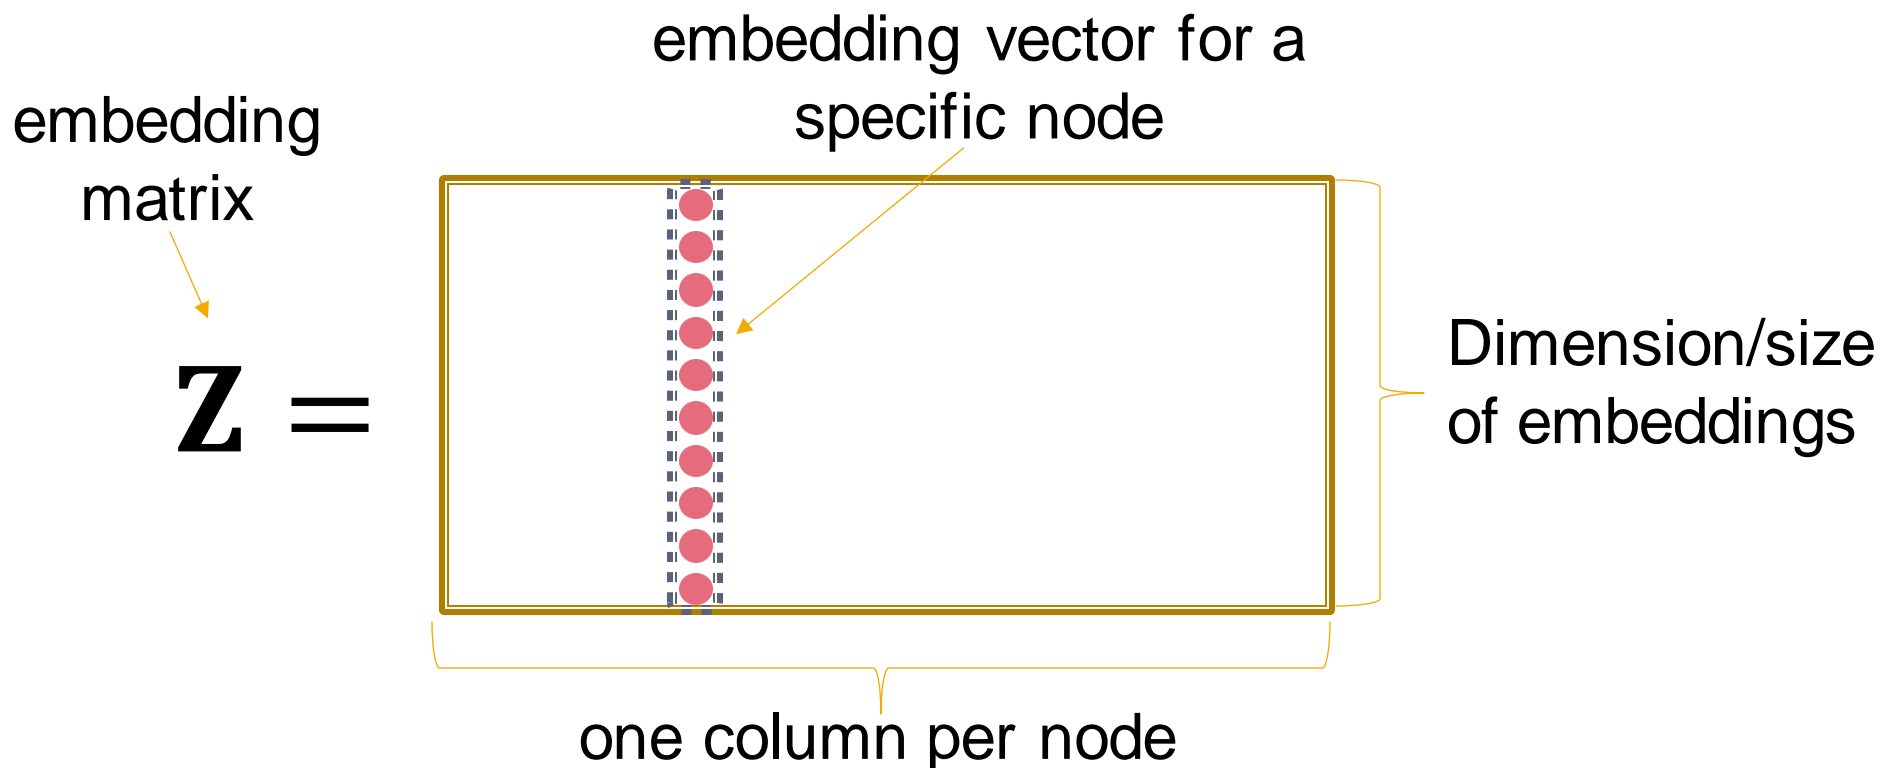

Stanford CS224W: Matrix Factorization and Node Embeddings

CS224W: Machine Learning with Graphs
Jure Leskovec, Stanford University
<http://cs224w.stanford.edu>

Embeddings & Matrix Factorization

- **Recall:** encoder as an embedding lookup

Objective: maximize $\mathbf{z}_v^T \mathbf{z}_u$ for node pairs (u, v) that are **similar**

Connection to Matrix Factorization

- Simplest **node similarity**: Nodes u, v are similar if they are connected by an edge
- This means: $\mathbf{z}_v^T \mathbf{z}_u = A_{u,v}$
which is the (u, v) entry of the graph adjacency matrix A
- Therefore, **$\mathbf{Z}^T \mathbf{Z} = A$**

Matrix Factorization

- The embedding dimension d (number of rows in \mathbf{Z}) is much smaller than number of nodes n .
- Exact factorization $\mathbf{A} = \mathbf{Z}^T \mathbf{Z}$ is generally not possible
- However, we can learn \mathbf{Z} approximately
- **Objective:** $\min_{\mathbf{Z}} \|\mathbf{A} - \mathbf{Z}^T \mathbf{Z}\|_2$
 - We optimize \mathbf{Z} such that it minimizes the L2 norm (Frobenius norm) of $\mathbf{A} - \mathbf{Z}^T \mathbf{Z}$
 - Note in Lecture 3 we used softmax instead of L2. But the goal to approximate \mathbf{A} with $\mathbf{Z}^T \mathbf{Z}$ is the same.
- Conclusion: **Inner product decoder with node similarity defined by edge connectivity is equivalent to matrix factorization of \mathbf{A} .**

Random Walk-based Similarity

- **DeepWalk** and **node2vec** have a more complex **node similarity** definition based on random walks
- **DeepWalk** is equivalent to matrix factorization of the following complex matrix expression:

$$\log \left(\text{vol}(G) \left(\frac{1}{T} \sum_{r=1}^T (D^{-1}A)^r \right) D^{-1} \right) - \log b$$

- Explanation of this equation is on the next slide.

[Network Embedding as Matrix Factorization: Unifying DeepWalk, LINE, PTE, and node2vec](#), WSDM 18

Random Walk-based Similarity

Volume of graph

$$\text{vol}(G) = \sum_i \sum_j A_{i,j}$$

Diagonal matrix D

$$D_{u,u} = \text{deg}(u)$$

$$\log \left(\text{vol}(G) \left(\frac{1}{T} \sum_{r=1}^T (D^{-1}A)^r \right) D^{-1} \right) - \log b$$

context window size

See Lec 3 slide 30:

$$T = |N_R(u)|$$

**Power of normalized
adjacency matrix**

**Number of
negative samples**

- **Node2vec** can also be formulated as a matrix factorization (albeit a more complex matrix)
- Refer to the paper for more details:

Network Embedding as Matrix Factorization: Unifying DeepWalk, LINE, PTE, and node2vec, WSDM 18

Limitations (1)

Limitations of node embeddings via matrix factorization and random walks

- Cannot obtain embeddings for nodes not in the training set

Training set

A newly added node 5 at test time
(e.g., new user in a social network)

**Cannot compute its embedding
with DeepWalk / node2vec. Need to
recompute all node embeddings.**

Limitation (2)

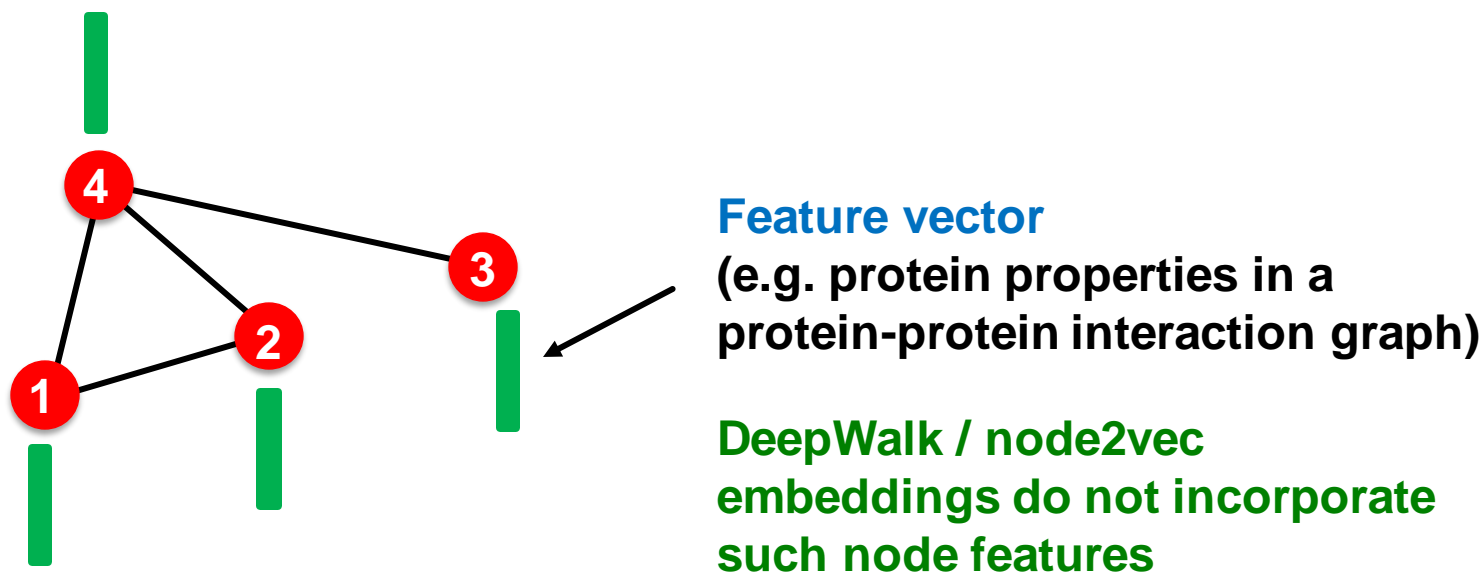

- Cannot capture **structural similarity**:

- Node 1 and 11 are **structurally similar** – part of one triangle, degree 2, ...
- However, they have very **different** embeddings.
 - It's unlikely that a random walk will reach node 11 from node 1.
- **DeepWalk and node2vec do not capture structural similarity.**

Limitations (3)

- Cannot utilize node, edge and graph features

Solution to these limitations: Deep Representation Learning and Graph Neural Networks
(To be covered in depth next week)

Summary

- **PageRank**
 - Measures importance of nodes in graph
 - Can be efficiently computed by **power iteration of adjacency matrix**
- **Personalized PageRank (PPR)**
 - Measures importance of nodes with respect to a particular node or set of nodes
 - Can be efficiently computed by **random walk**
- **Node embeddings** based on random walks can be expressed as **matrix factorization**
- **Viewing graphs as matrices plays a key role in all above algorithms!**
